Net 2818

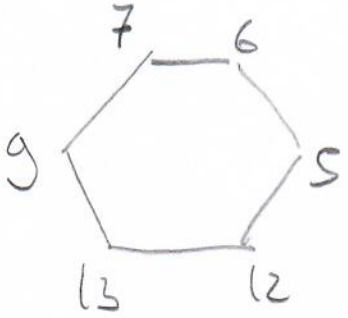

We draw a diagram of the net

Since the edges 8'10' and '10''11' are congruent the pentagon 348'10''11' is symmetric with respect to the equator γ containing 109 The same applies to 01234, in particular γ contains S1 as well

Consider the edge 76. We claim that it stays in the upper half sphere bounded by γ. This is obvious because 38762 is a convex pentagon. By symmetry if we draw the edge connecting 13 and 12, it bisects both 13 and 12.

This forms an hexagon with angles $\frac{2\pi}{3}$:

But the latter does not exist
