1177

Consider the subset P_1

The points 5, 3, 2, and 0 are on the equator & which bisects the bi-angle

Replace the edge // to make an outer face which is a {5, 2} pentagon and still contains the region Ω

In this new face F, which has area $\frac{5\pi}{3}$, the edge SO is larger than π. Pick on it the antipodal of S.

Keeping S and S' move the half equator SS' until it hits the pin

The area swept by this

is $\frac{4\pi}{3}$ and the region is extended to Ω. Moreover Ω has area $\frac{\pi}{3}$

The seam is $\frac{5\pi}{3}$ but the face contains strictly more while its area is exactly $\frac{5\pi}{3}$
