899

The diagram is

Consider that 2, 3, 5, and 6 are all on the equator & that bisects the biangle

Let C be the center of the triangle 104. The geodesic segment 5C is outside the triangle because 50 is an edge external to the triangle and OC is inside the triangle

Likewise 6C is also outside the triangle for the same reason

So SO and GC must be strictly shorter than π: they have one vertex in γ; if they were $\geq \pi$ they would contain its antipodal, which is in the triangle. Let H^+ and H^- be the half spheres delimited by γ. Then C must be in H^+, because GC enters in it and cannot leave H^+, and in H^-, because SC enters in H^- and does not leave it.
